Contents

1 Introduction

For a growing number of applications, it will be crucial to acquire data in a smart way. One way to achieve this goal is to build a smart microscope, which essentially means creating smart software workflows to control the hardware based on image analysis results.

Idea or Task:

- Scan or inspect a large area.
- Detect an "interesting" object.
- Acquire detailed data for every event.
- Automate the workflow to minimize user interference.

First of all it is important to define what a **Object of Interest** can actually be. Example would be an object that meets specific criteria, for example:

- size
- brightness
- shape
- intensity
- combinations of the above

It could be something quite simple. For instance one can have lots of cells, that are stained with blue dye, and only a few of them (maybe where the transfection worked ...) are also expressing GFP. The idea here would be to detect all cells that are positive for both colors and acquire an z-Stack for every cell (blue & green) that meets those criteria. Therefore this kind of application requires three major tasks:

1. **Define the Overview Scan Experiment.**
2. **Define the object detection rules, e.g. setup image analysis.**
3. **Define the Detailed Scan(s) to be carried out in case of a "positive" object.**

1.1 Basic Workflow Definition

The main workflow can be summarized as follows:

1. Acquire some sample data showing a object of interest.
2. Setup an Image Analysis Pipeline to detect those events.
3. Define an experiment which does the Overview Scan.
4. Define an experiment which does the Detailed Scan.

5. Automate the entire workflow.

The goal of this tutorial is to create an automated workflow that can be used to easily setup a **Guided Acquisition**. This requires some knowledge about the OAD macro environment and its scripting language Python.

1.2 General Workflow Definition

This is the outline of the general workflow, which would be automated.

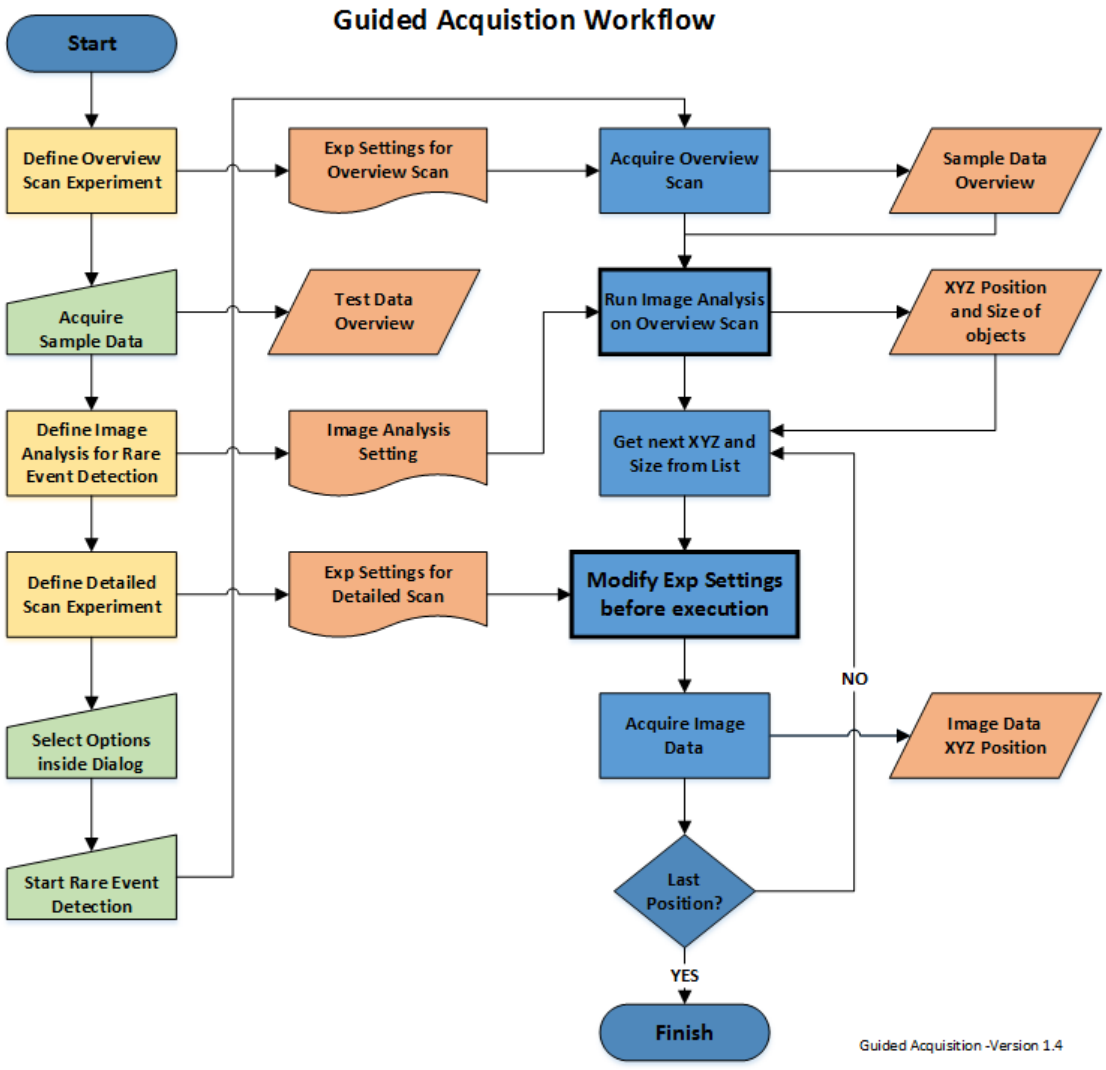

Figure 1: General workflow for Guided Acquisition.

A different way to visualize this is shown in the figure below.

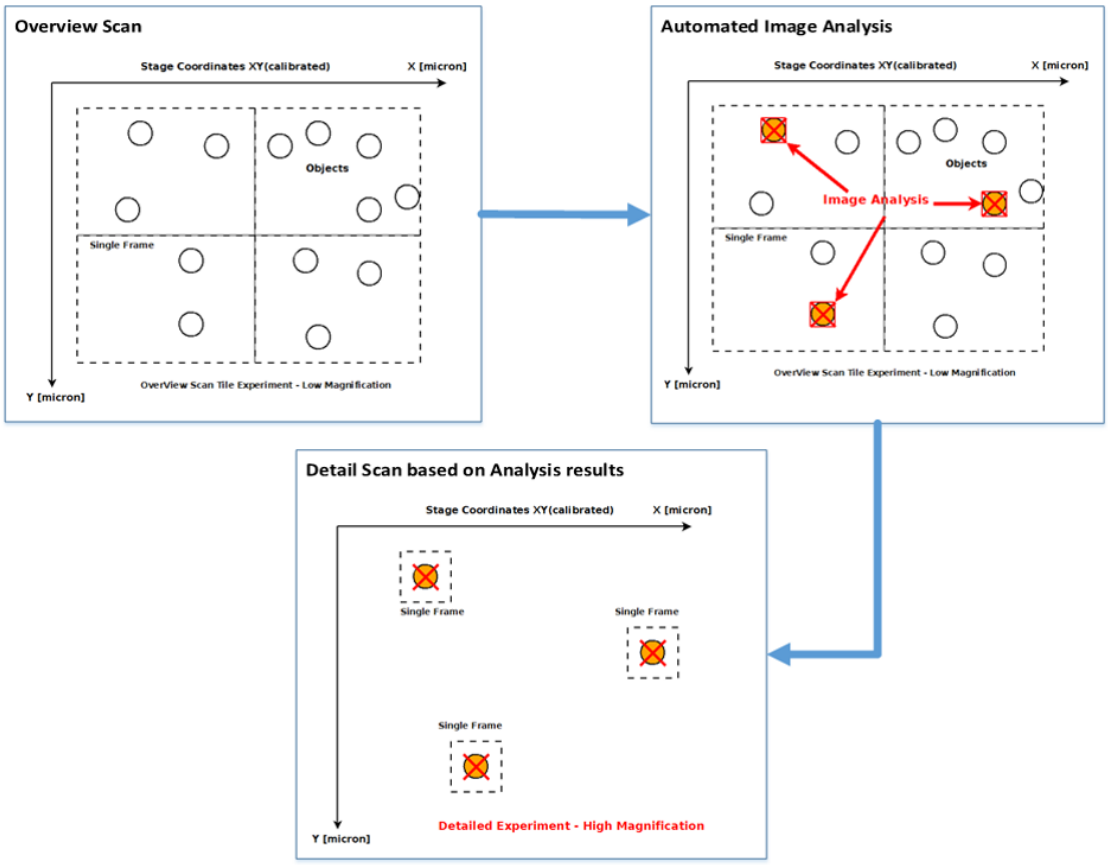

Figure 2: Larger area with some candidates for a "interesting" objects.

1.3 General Workflow - Complete Overview

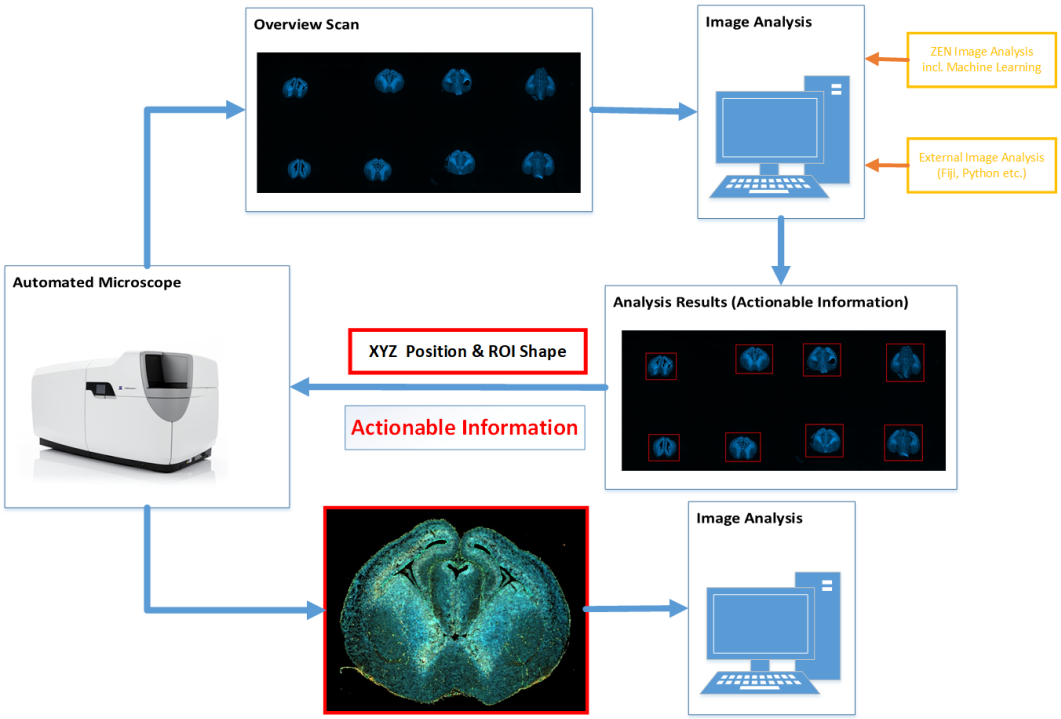

Figure 3: Workflow - Actionable Information 1.

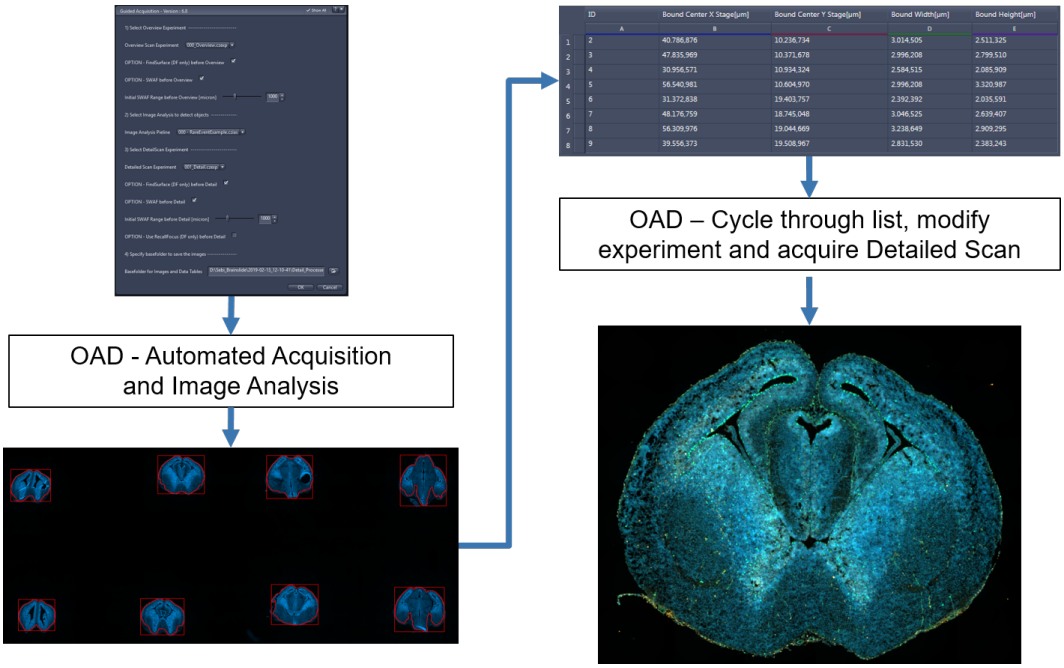

Figure 4: Workflow - Actionable Information 2

2 Workflow - Single Steps

This part of the tutorial will explain all required steps to set up the complete workflow in more detail. Some knowledge about image analysis is required here.

2.1 Acquire Sample Data with Overview Scan

The first crucial step is to have a basic idea of what the actual rare event will look like, inside an real image acquired, with the appropriate parameters (light intensity, detector settings, filters, objective, ...). An ideal sample data set should be acquired using the "real" acquisition parameters will be used to define the overview scan experiment later on.
Typically such an overview scan is acquired using a lower magnification in combination with a tile experiment. The exact parameters will be specific for the application, but the main idea is always the same:

The overview image must contain the information to locate the objects of interest based on "some" features that can be retrieved via an appropriate image analysis.

Once a representative sample data set is available, one can start setting up an image analysis pipeline. ZEN offers currently two ways do to so:

1. The easy way – Use the Analysis Wizard.
2. Program your own image analysis pipeline using an OAD macro (this is not covered by this tutorial).
3. Program your own image analysis using an external software (e.g. Fiji, Python etc.) and use it from within ZEN (this is not covered by this tutorial).

The most comfortable way is to use the wizard; this offers enough flexibility to cover most of the applications.

2.2 Create Image Analysis Pipeline

Here one already sees a "half-ready" image analysis pipeline. In order to automate, the wizard step containing the feature selection is crucial.

In order to relocate all detected objects, it is of course required to retrieve the current XY(Z) position of every detected event.

The main idea is to determine all parameters required to get access to the stage coordinates of a detected object.

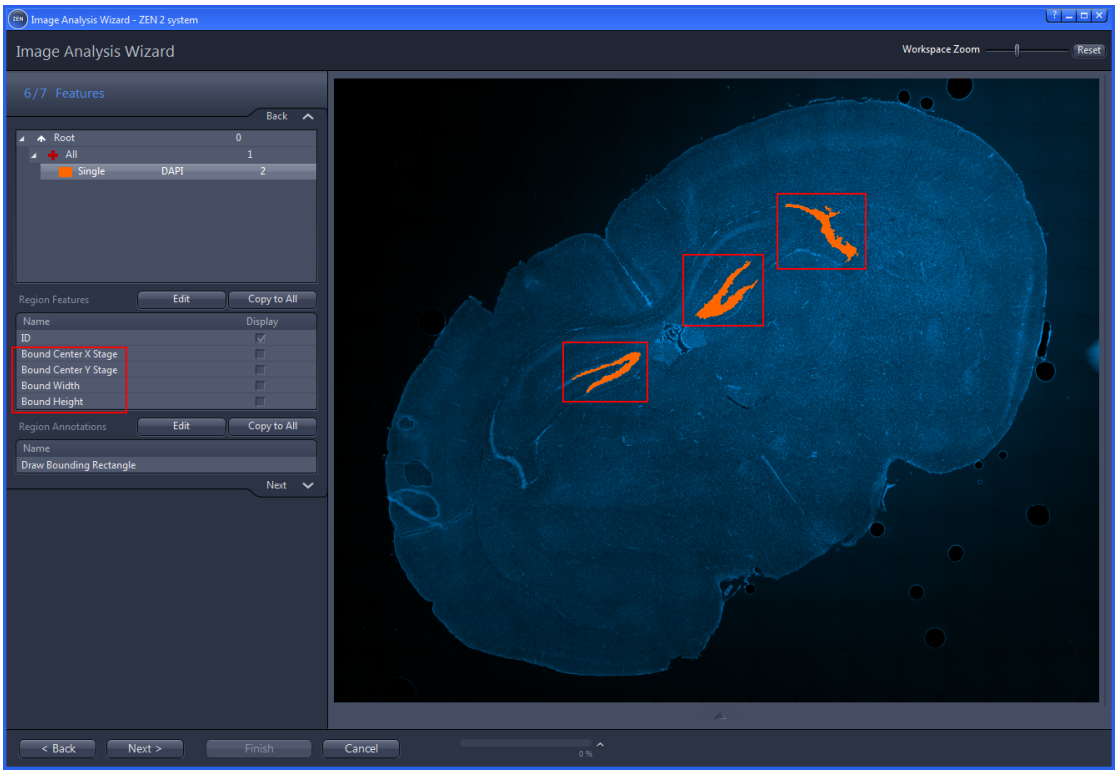

Figure 5: Select the required positional features inside the wizard.

Currently one needs to select the following parameters:

- Object ID
- Bound Center Stage X
- Bound Center Stage Y
- Bound Width
- Bound Height
- ImageSceneContainerName

The object ID is needed to keep track of the executed detail scans and to save the resulting image files with the correct ID as part of the used filename.

The parameters **Bound Center Stage X** and **Bound Stage Center Y** yield absolute stage coordinates of the detected objects. These will be used to relocate the objects for the detailed scan later on.

The parameters **Bound Width** and **Bound Height** yield in the absolute width and height of the bounding rectangle. This is required if the detected object is bigger than a single frame. In such a case the tile region of the detailed experiment will be adapted to the size of the bounding rectangle automatically.

The parameter **ImageSceneContainerName** is needed to keep track of the respective wells, because the wellID will be used as part of the filename for the detail scan. Depending on your application, it might be useful to measure additional parameters. Feel free to add whatever might be useful.

2.3 Define Overview Experiment

Usually this is done using the Tiles and Positions module to scan a large area. This tutorial assumes that one is already familiar with this ZEN module.

Important Remark: Since one wants to relocate the detected objects, it is required to calibrate the XY stage before the overview scan, and a rigid and stiff sample holder should be used.

For this tutorial one can use an already acquired image representing the real overview scan (instead of a real experiment). The shown image is a 16x13 tile image acquired with a 10X magnification. The result of such a scan followed by the image analysis is shown here:

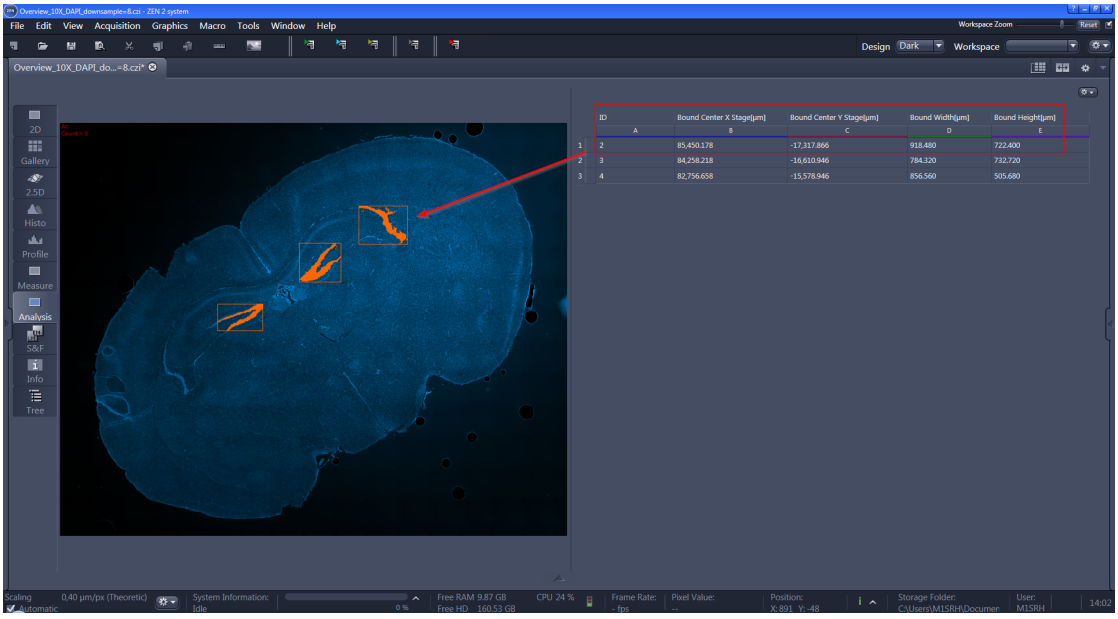

Figure 6: Result of the image analysis on the overview scan image.

2.4 Define Detailed Scan Experiment

First of all it is important to understand, that there is no such thing as a typical "Detailed Scan". What this experiment (or even a workflow) might be, depends on the application. In a general sense such a detailed scan is "some kind" of experiment carried at a specific position based upon the results of the image analysis. Examples could be:

- Simple Z-Stack with a high-NA objective lens.
- Multi-Channel Z-Stack using an optical sectioning method like SD, Apotome or AiryScan
- One of the above combined with a tile experiment.
- A series of subsequent experiments with different image modalities.

Since this concept is based on OAD, it is possible to automated almost any kind of workflow at a given position.

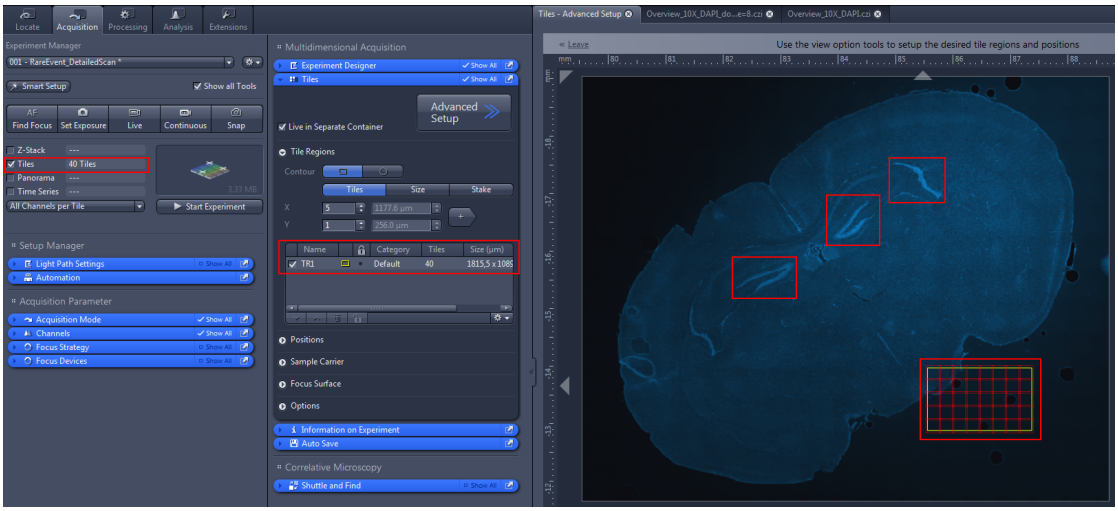

Figure 7: Setup of a simple detailed scan experiment.

Now the preparation is complete. So far we have available:

- The image analysis pipeline based on some sample data
- The Overview Scan Experiment = tile experiment created by the Tiles & Positions Module
- The Detailed Scan Experiment, which is also a tile experiment.

And now the real interesting part begins – how to setup a complete workflow out of those building blocks using an OAD Python script inside ZEN Blue.

3 Automation via OAD

3.1 Prerequisites

In order to be able to run the script one needs to copy it into the correct folder, which is located at:

"c:/Users/XXXX/Documents/Carl Zeiss/ZEN/Documents/Macros"

where XXXX stand for the actual user name.

3.2 Pure Scripting or User Dialog

First of all one has to decide if a pure script is sufficient or if there should be some kind of simple user interface (very basic wizard).

- A pure script is of course the faster solution, but is may be difficult to use for less advanced users.
- A basic wizard offers less flexibility, but may be easier to use for most users.

The choice clearly depends on the user, since there is no right or wrong approach here. For this tutorial we will focus on the 2nd approach. Once one has figured out how to realize this, the 1st approach will be straight forward since the basic workflow is identical.

3.3 User Dialog Requirements

The basic user interface of the dialog should have the following functionality:

- **Select the overview scan experiment.**
- **Select the image analysis pipeline** (to analyze the overview image)
- **Select the detailed scan experiment** (to acquire at "found" positions)
- **Define options for focussing** (depends on available hardware)
- **Select a folder to store the image data and analysis results.**

3.4 Prerequisites

Now we are ready to create the OAD macro required to control the complete workflow. The first step is (as always) to import the required modules and define the folder locations, etc. Additionally there are several python functions defined here for later usage.

```

170             break
171 
172     return entry_exits, column
173 
```

3.5 Create the User Dialog

The next task is to create the user dialog using the requirements referred to earlier on. Once the dialog is closed, the results have to be collected.
Additionally one must check if the Detailed Scan experiment is a tile experiment, where the tile size has to be adapted accordingly. This is done using a little tool function.

```
193 # Initialize Dialog
194 GuidedAcqDialog = ZenWindow()
195 GuidedAcqDialog.Initialize('Guided Acquisition - Version : ' + str(version))
196 # add components to dialog
197 GuidedAcqDialog.AddLabel('1) Select Overview Experiment  ------------------------------')
198 GuidedAcqDialog.AddDropDown('overview_exp', 'Overview Scan Experiment', expfiles_short, 0)
199 GuidedAcqDialog.AddCheckbox('fs_before_overview', 'OPTION - FindSurface (DF only) before Overview', False)
200 GuidedAcqDialog.AddCheckbox('SWAF_before_overview', 'OPTION - SWAF before Overview', False)
201 GuidedAcqDialog.AddIntegerRange('SWAF_ov_initial_range', 'Initial SWAF Range before Overview [micron]', 200, 50, 3000)
202 GuidedAcqDialog.AddLabel('2) Select Image Analysis to detect objects  ----------------------')
203 GuidedAcqDialog.AddDropDown('ip_pipe', 'Image Analysis Pieline', ipfiles_short, 0)
204 GuidedAcqDialog.AddLabel('3) Select DetailScan Experiment  --------------------------')
205 GuidedAcqDialog.AddDropDown('detailed_exp', 'Detailed Scan Experiment', expfiles_short, 1)
206 GuidedAcqDialog.AddCheckbox('fs_before_detail', 'OPTION - FindSurface (DF only) before Detail', False)
207 GuidedAcqDialog.AddCheckbox('SWAF_before_detail', 'OPTION - SWAF before Detail', False)
208 GuidedAcqDialog.AddIntegerRange('SWAF_detail_initial_range', 'Initial SWAF Range before Detail [micron]', 100, 10, 1000)
209 GuidedAcqDialog.AddCheckbox('recallfocus_beforeDT', 'OPTION - Use RecallFocus (DF only) before Detail', False)
210 GuidedAcqDialog.AddLabel('4) Specify basefolder to save the images ----------------------')
211 GuidedAcqDialog.AddFolderBrowser('outfolder', 'Basefolder for Images and Data Tables', imgfolder)
212
213 # show the window
214 result = GuidedAcqDialog.Show()
215 if result.HasCanceled:
216     message = 'Macro was canceled by user.'
217     print(message)
218     raise SystemExit
219
220 # get the values and store them
221 OverViewExpName = str(result.GetValue('overview_exp'))
222 ImageAS = str(result.GetValue('ip_pipe'))
223 DetailExpName = str(result.GetValue('detailed_exp'))
224 OutputFolder = str(result.GetValue('outfolder'))
225 fs_beforeOV = result.GetValue('fs_before_overview')
226 SWAF_beforeOV = result.GetValue('SWAF_before_overview')
227 SWAF_beforeOV_range = result.GetValue('SWAF_ov_initial_range')
228 fs_beforeDT = result.GetValue('fs_before_detail')
229 SWAF_beforeDT = result.GetValue('SWAF_before_detail')
230 SWAF_beforeDT_range = result.GetValue('SWAF_detail_initial_range')
231 RecallFocus = result.GetValue('recallfocus_beforeDT')
232
```

The resulting dialog window is shown below.

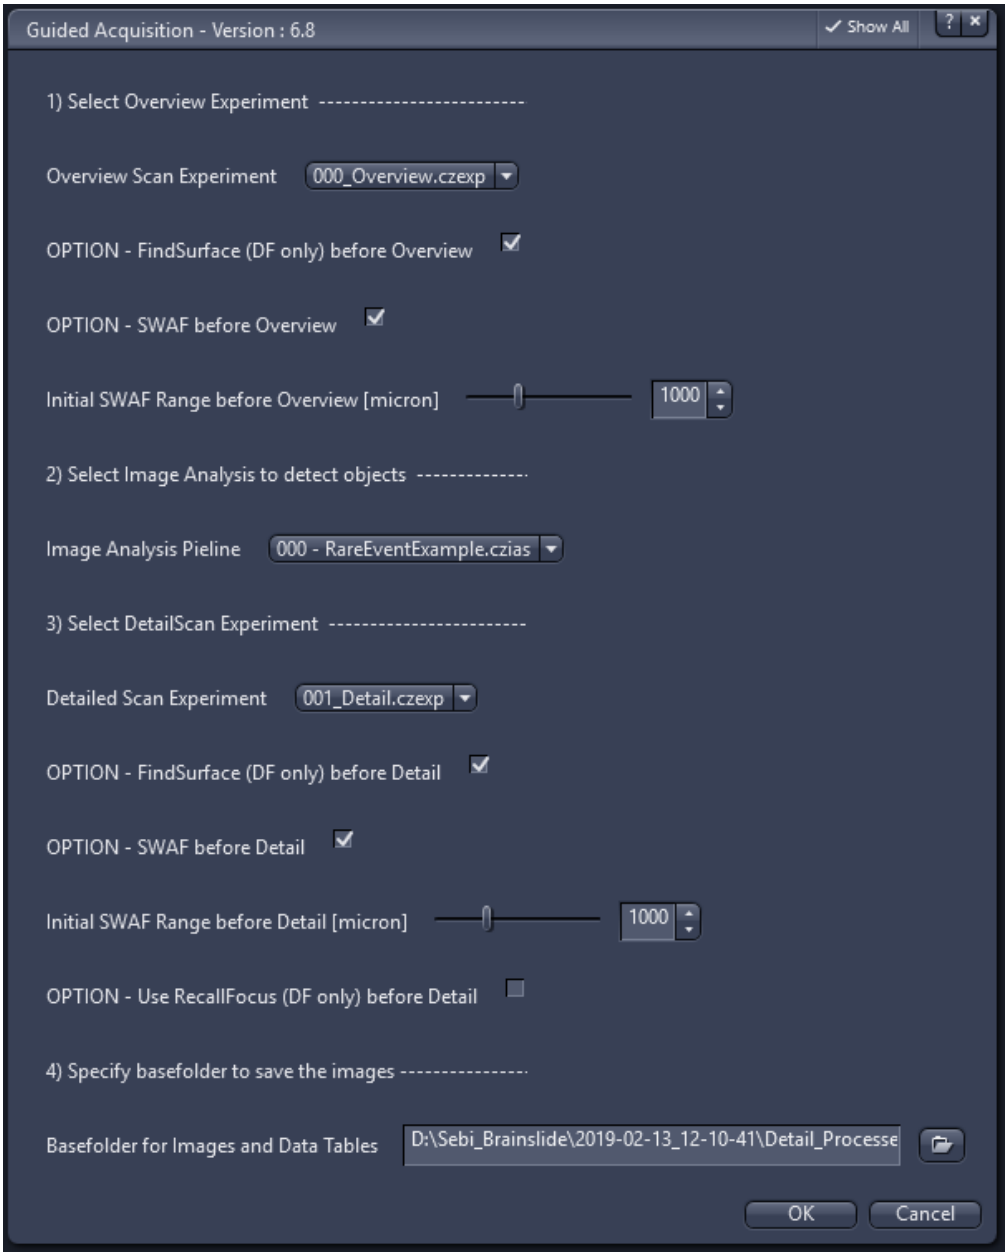

Figure 8: Simple User Dialog to run the Guided Acquistion WorkFlow

The dialog has four main steps where the user must define the desired options:

1. Select **overview experiment** and additional focus options.
2. Select **image analysis** to detect the objects.
3. Select **detailed experiment** and additional focus options.
4. Choose an **output folder** to save the data.

3.6 Overview Scan Experiment

At this point we have all the information we need to actually start the workflow. The first step is to execute the actual overview scan experiment, which is most likely a tile experiment. The resulting image will be saved to the specified folder.

```
############ START OVERVIEW SCAN EXPERIMENT #################

if fs_beforeOV:
    # initial focussing via FindSurface to assure a good starting position
    Zen.Acquisition.FindSurface()
    print('Z-Position after FindSurface: ', Zen.Devices.Focus.ActualPosition)

if SWAF_beforeOV:
    zSWAF = runSWAF_special(OVScan_reloaded,
                            delay=hwdelay,
                            searchStrategy='Full',
                            sampling=ZenSoftwareAutofocusSampling.Coarse,
                            relativeRangeIsAutomatic=False,
                            relativeRangeSize=SWAF_beforeOV_range,
                            timeout=1)

# get the resulting z-position
znew = Zen.Devices.Focus.ActualPosition

# adapt the Overview Scan Tile Experiment with new Z-Position
if OVScanIsTileExp:
    OVScan_reloaded.ModifyTileRegionsZ(blockindex, znew)
    print('Adapted Z-Position of Tile OverView. New Z = ', '%.2f' % znew)

# execute the experiment
print('\nRunning OverviewScan Experiment.\n')
output_OVScan = Zen.Acquisition.Execute(OVScan_reloaded)
# For testing purposes - Load overview scan image automatically instead of executing the "real" experiment
# output_OVScan = Zen.Application.LoadImage(r'c:\Temp\input\OverViewScan_8Brains.czi', False)

# show the overview scan inside the document area
Zen.Application.Documents.Add(output_OVScan)
ovdoc = Zen.Application.Documents.GetByName(output_OVScan.Name)

# save the overview scan image inside the select folder
output_OVScan.Save(Path.Combine(OutputFolder, ovscan_name))

############ END OVERVIEW SCAN EXPERIMENT ##################
```

A very important part of such an automated workflow is to find the focus. To ensure this, the desired objective and optovar are changed before the overview starts, followed by a series of **optional** focus actions:

1. Find the surface of the sample carrier.
2. Focus onto the specimen sample via SWAF.
3. Store the resulting new Z-position.

When testing out applications like this it is very useful to use test data sets to save time instead of re-running an acquisition many times. Therefore it can be helpful to **comment** the lines where the real experiment is executed and **uncomment** the line inside the script, where one can load an already acquired overview image.

3.7 Find the interesting Objects

Now it is time to run the image analysis on the overview image. As a result, two tables will be created inside ZEN. The first contains information about all objects and the second contains information about the single objects (for instance their stage positions). This second table is what will be used as an input for the detailed scan later on.

```
292 # Load analysis setting created by the wizard or an separate macro
293 ias = ZenImageAnalysisSetting()
294
295 # for simulation use: 000 - RareEventExample.czias
296 ias.Load(ImageAS)
297
298 # Analyse the image
299 Zen.Analyzing.Analyze(output_OVScan, ias)
300
301 # Create Zen table with results for all detected objects (parent class)
302 AllObj = Zen.Analyzing.CreateRegionsTable(output_OVScan)
303
304 # Create Zen table with results for each single object
305 SingleObj = Zen.Analyzing.CreateRegionTable(output_OVScan)
306
307 # check for existence of required column names inside table
308 soi = SingleObj.GetBoundsColumnInfoFromImageAnalysis(True)
309
310 # 1st item is a bool indicating if all required columns could be found
311 columnsOK = soi.AreRequiredColumnsAvailabe
312
313 if not columnsOK:
314     print('Execution stopped. Required Columns are missing.')
315     raise Exception('Execution stopped. Required Columns are missing.')
316
317 # show and save data tables to the specified folder
318 Zen.Application.Documents.Add(AllObj)
319 Zen.Application.Documents.Add(SingleObj)
320 AllObj.Save(Path.Combine(OutputFolder, 'OverviewTable.csv'))
321 SingleObj.Save(Path.Combine(OutputFolder, 'SingleObjectsTable.csv'))
322
323 # check the number of detected objects = rows inside image analysis table
324 num_POI = SingleObj.RowCount
325
```

As shown in figure **5**, it is required to have the correct image analysis features selected. Only the will the respective columns inside the table exist. This has to be checked because otherwise the workflow will be impossible.

The "checking" itself is again done by a tool function. The output will be a boolean and a dictionary in order to look up the column index for the respective image analysis parameters. This has the advantage of being independent from a specific column order. One just has to make sure that all required columns are there.

If the option inside the initial dialog window was checked, the offset between the sample carrier surface and the actual specimen will be measured and stored inside the Definite Focus via **Store Focus**, so that **Recall Focus** can be used later on when needed. The dialog also offers the possibility to enter an arbitrary offset manually, which will only be applied if the offset was not determined automatically.

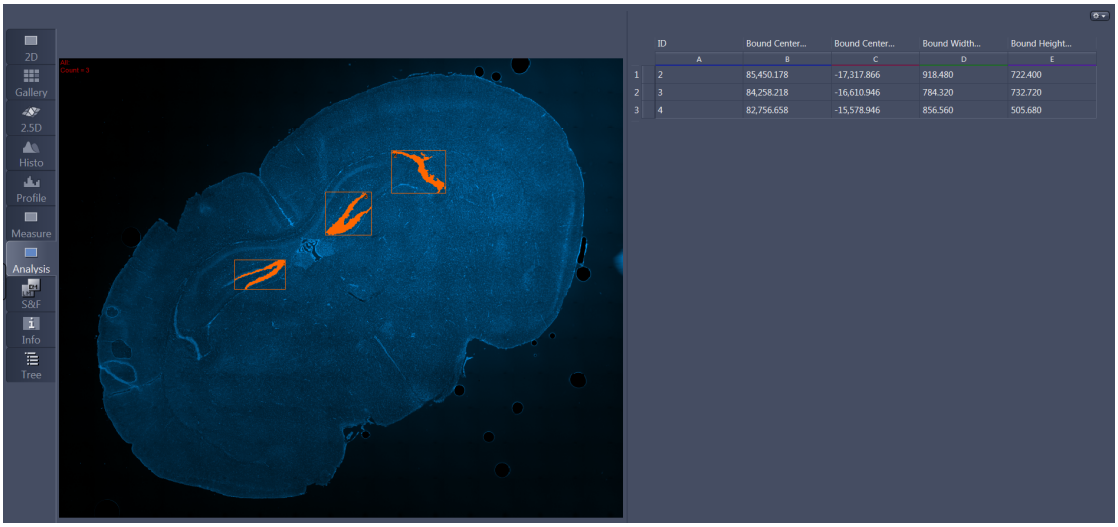

Figure 9: The results of the overview scan and the image analysis.

Finally the number of detected objects is checked by looking up the number of rows inside the table containing the information about the single objects.

3.8 Modify the Tile Dimensions

Once one has the list of objects with the stage coordinates, the next task is to create a loop to cycle through all detected positions.

- Move to the correct XYZ stage positions.
- Run Focus Actions when required.
- Initialize the DetailScan experiment at the new position.
- Adapt TilePosition using *Tiles.TileTools.ModifyTileRegionsXYZ*.
- Modify TileSize using *Tiles.TileTools.ModifyTileRegionsSize*.

```
382 ############# START DETAILED SCAN EXPERIMENT #############
383
384 # get the actual Focus position
385 zpos = Zen.Devices.Focus.ActualPosition
386
387 # check for the column 'ID' which is required
388 ID_exits, column_ID = checktableentry(SingleObj,
389                                       entry2check='ID')
390
391
392 # execute detailed experiment at the position of every detected object
393 for i in range(0, num_POI, 1):
394
395     # get the object information from the position table
396     # get the ID of the object - IDs start with 2 !!!
397     #POI_ID = SingleObj.GetValue(i, 0)
398     POI_ID = SingleObj.GetValue(i, column_ID)
399
400     # get XY-stage position from table
401     xpos = SingleObj.GetValue(i, soi.CenterXColumnIndex)
402     ypos = SingleObj.GetValue(i, soi.CenterYColumnIndex)
403
404     # move to the current position
405     Zen.Devices.Stage.MoveTo(xpos + dx_detector, ypos + dy_detector)

484 
485 ############# END DETAILED SCAN EXPERIMENT #############
486 
```

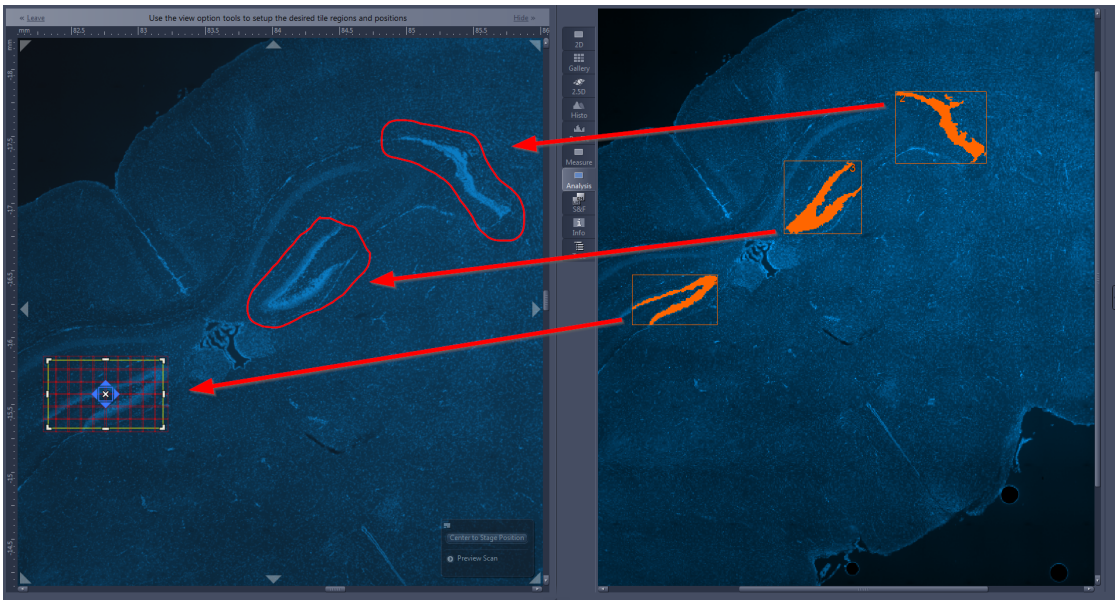

Figure 10: The results of the detailed scan - tile regions adapts to objects.

That is it. All image data sets acquired at the detected positions are stored inside the correct folder using the object IDs as names. The tables are saved in the same location.

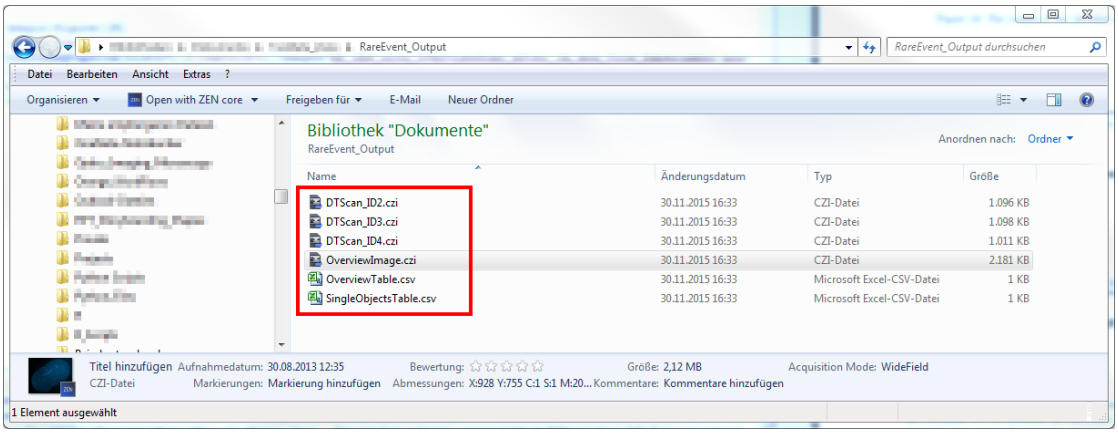

Figure 11: The results of the detailed scan stored inside a folder.

4 Testrun with FluoCells Slide

To test the workflow on a real sample one can use the FluoCells slide. The general idea is to setup an image analysis that detects some "interesting" objects. In order to create a somewhat short test run it is recommended to use an image analysis pipeline that only yields in a few positive detection events.

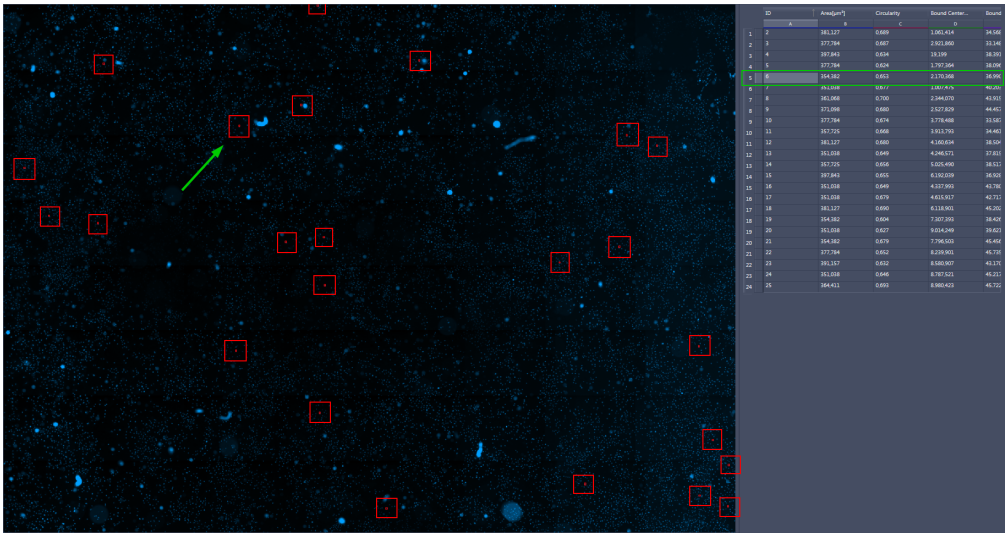

Figure 12: The results of the overview scan and image analysis.

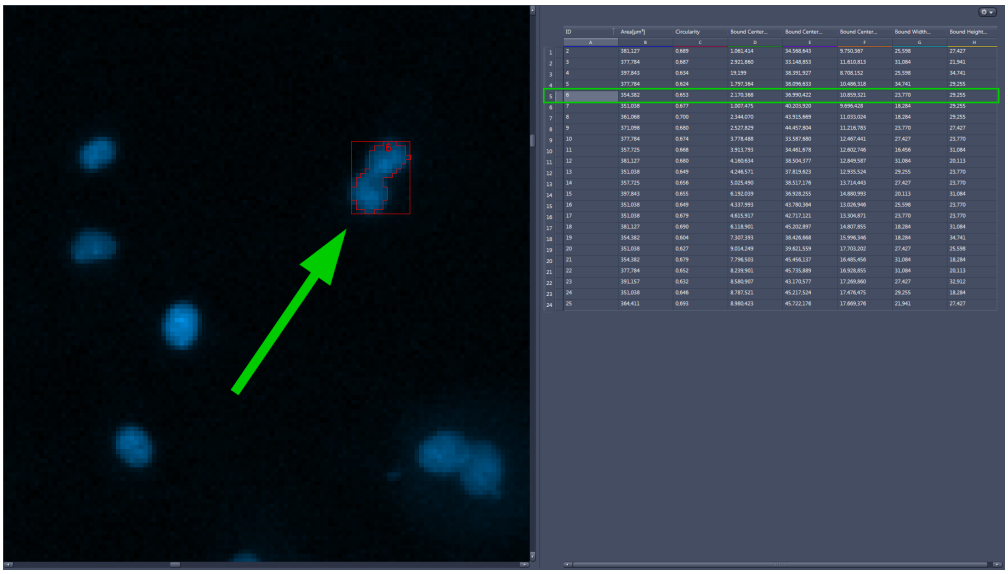

Figure 13: Detailed view on a detected object.

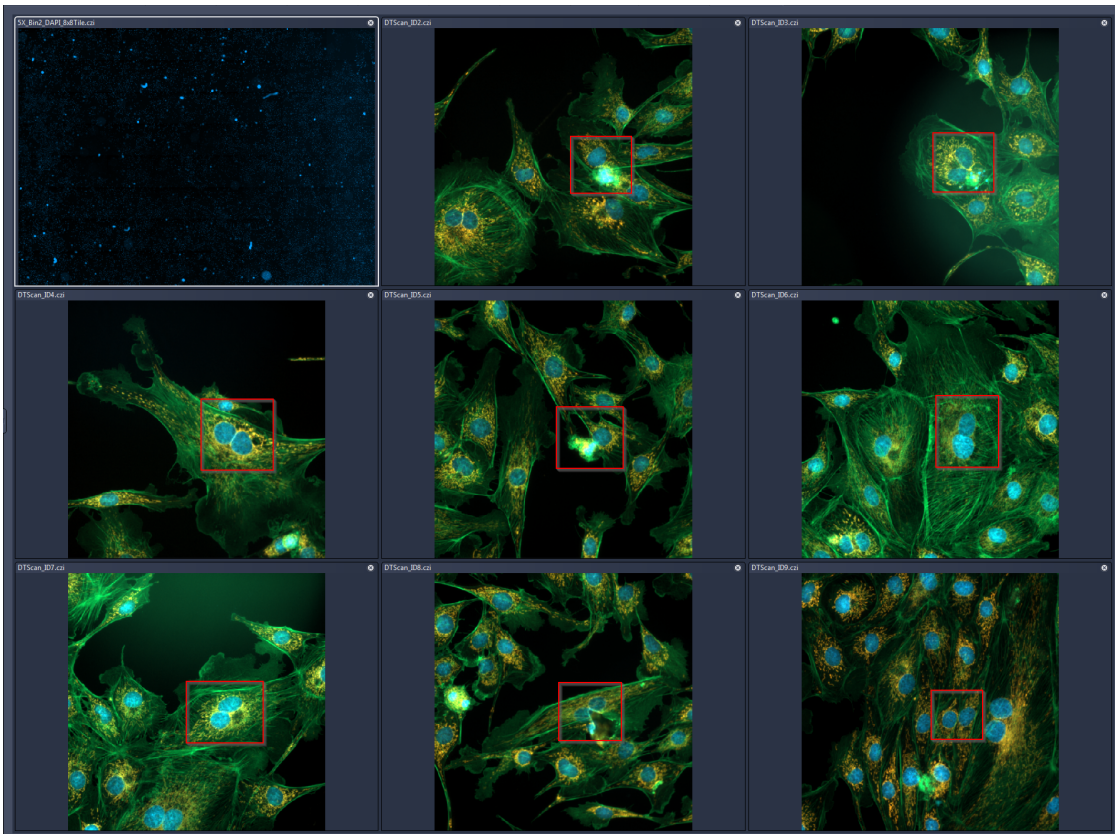

Figure 14: Detailed images from some of the detected objects.

The image analysis yielded **24** positive detections of cells with a large nucleus, preferably cells which were "caught" during cell division. Keep in mind, that the image analysis was not "fine-tuned" to catch all cell divisions. It is all about testing out the general workflow. For this reason it is also good practice to acquire a small overview scan at the beginning, e.g. a 2x2 tile image.

5 Test Run with Brain Slide

The same basic workflow can be also used to detect brain slices on a slide. All one needs to change is the image analysis pipeline in order to detect the slices.

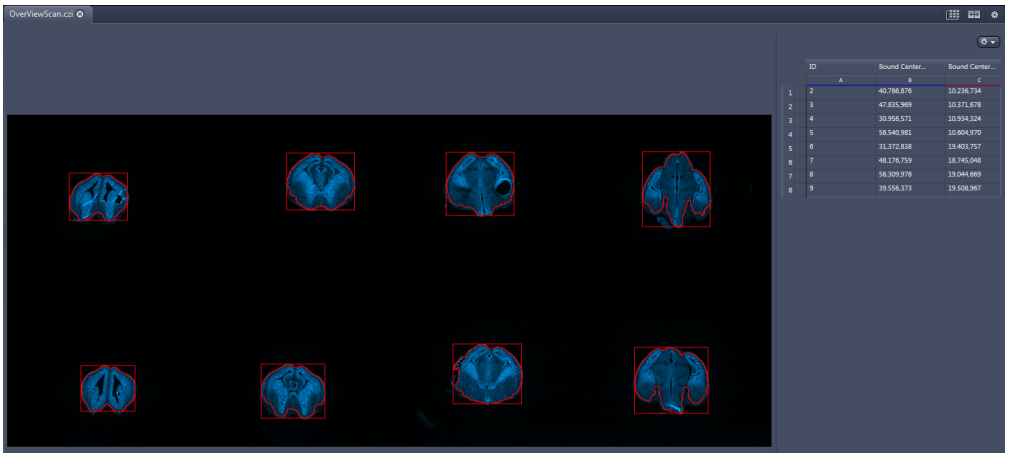

Figure 15: The results of the overview scan and image analysis.

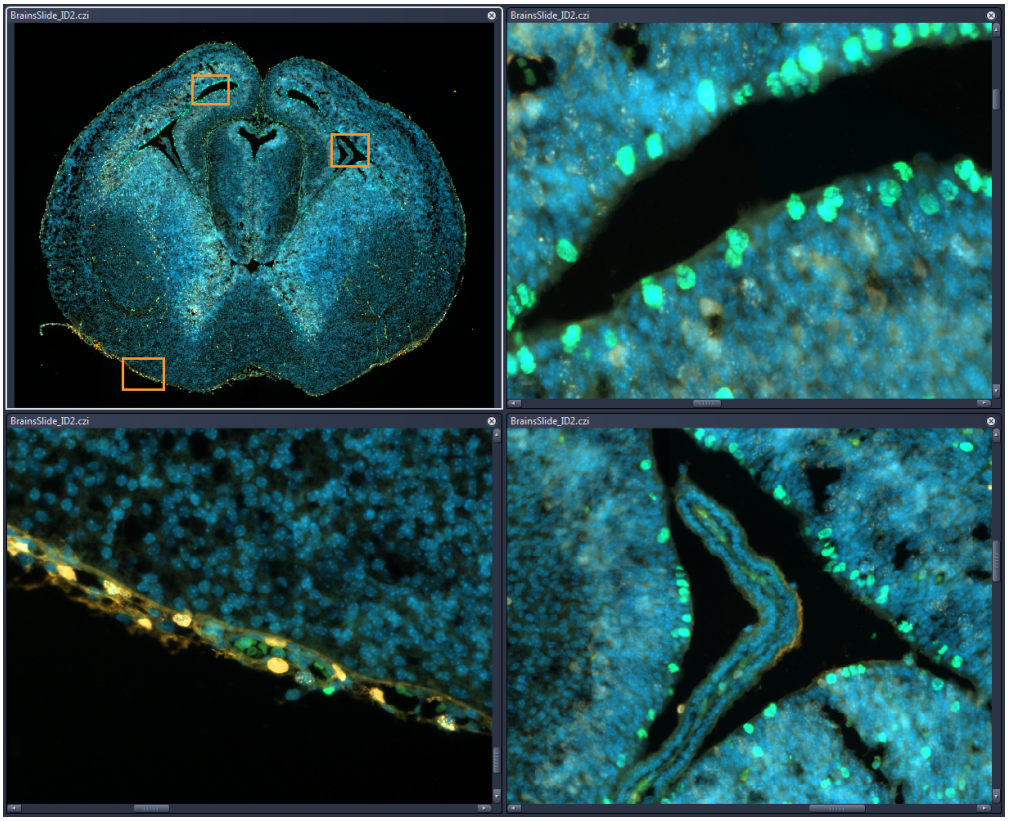

Figure 16: A more detailed image of the first specimen with three zoomed-in regions.

The image analysis yielded **eight** positive regions for brains slices on this slide. The properties of the bounding rectangle were used to modify the required tile experiment. The final detailed scan contained 36 tiles and it was imaged using only a hardware-based focus system.

Keep in mind that the actual focusing during such a experiment must be still part of the focus strategies with the Detail Scan experiment. Which one must be used here greatly depends on the nature of the sample and the actual application. The Guided Acquisition tool only supports finding the initial positions based on the overview scan image.

6 Mitosis Detection with Camera and LSM

An especially interesting option is to combine the power of a camera-based overview scan with the optional sectioning capabilities of an LSM. Such an workflow can be easily configured in ZEN Blue by setting up the respective experiment for the overview scan with camera detection using a low magnification and the LSM-based detail scan, e.g. Z-Stack, using a high NA objective.

Since ZEN Blue 2.5 this software has a module called **ZEN Connect**, which allows combining and correlating images inside one sample-centric workspace. Every acquired image by either the camera or the LSM) will be placed here based on the XY stage coordinates. Therefore the **Correlative Workspace (CWS)** is ideally suited to display the results of an Guided Acquisition workflow.

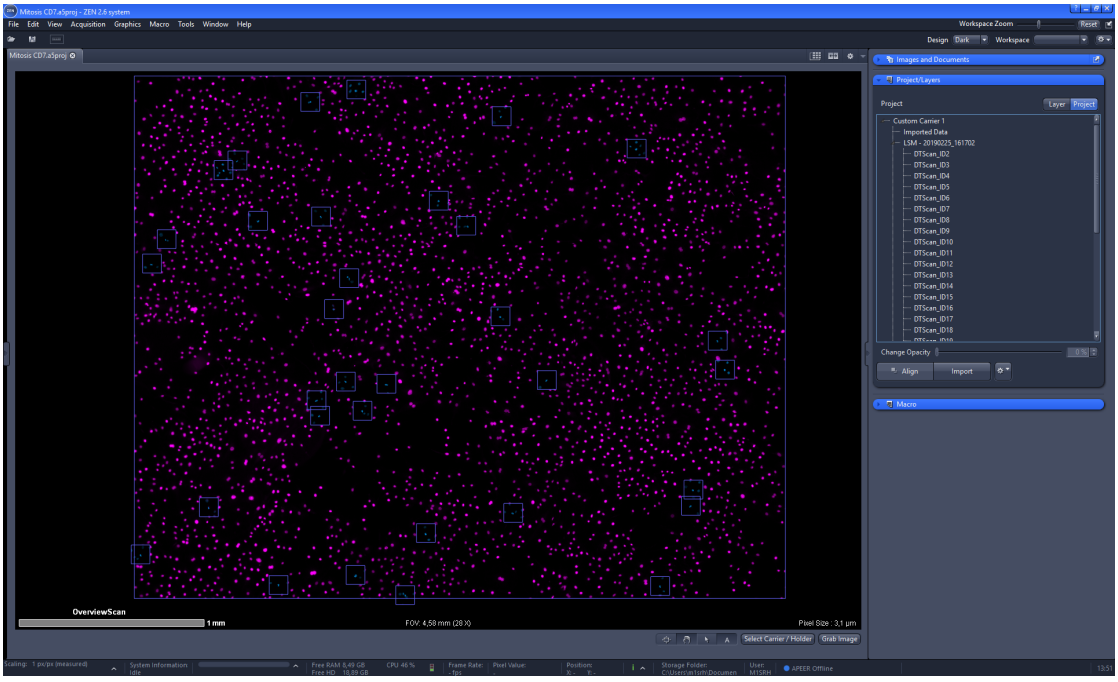

Figure 17: The results of the overview scan and image analysis inside the CWS.

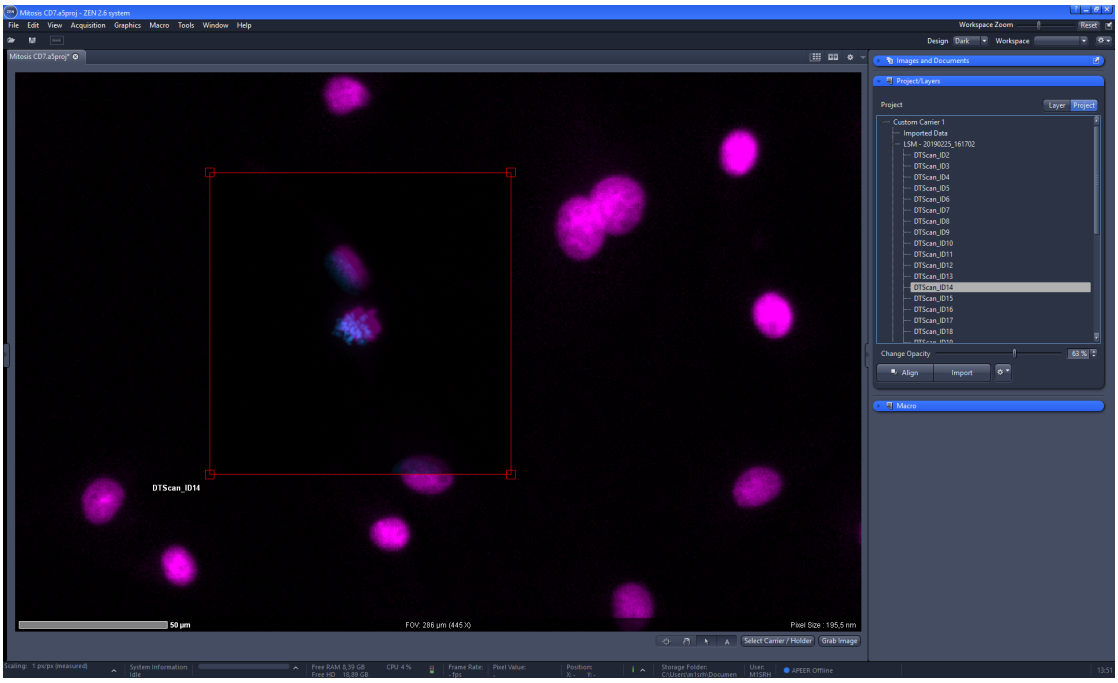

Figure 18: Overlay between positive detection inside overview scan and detailed scan using the Correlative Workspace (CWS).

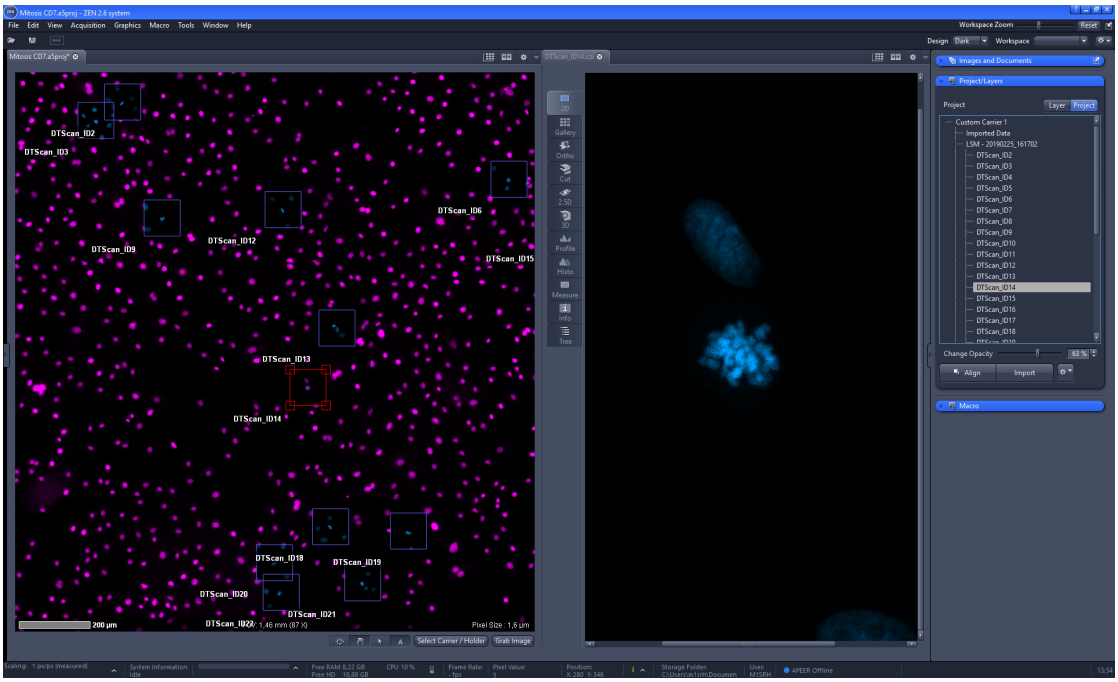

Figure 19: Side-by-Side view of the CWS and the normal view inside ZEN Blue.

7 Appendix

7.1 Complete Workflow Diagram

This is the complete workflow diagram for **Guided Acquisition**.

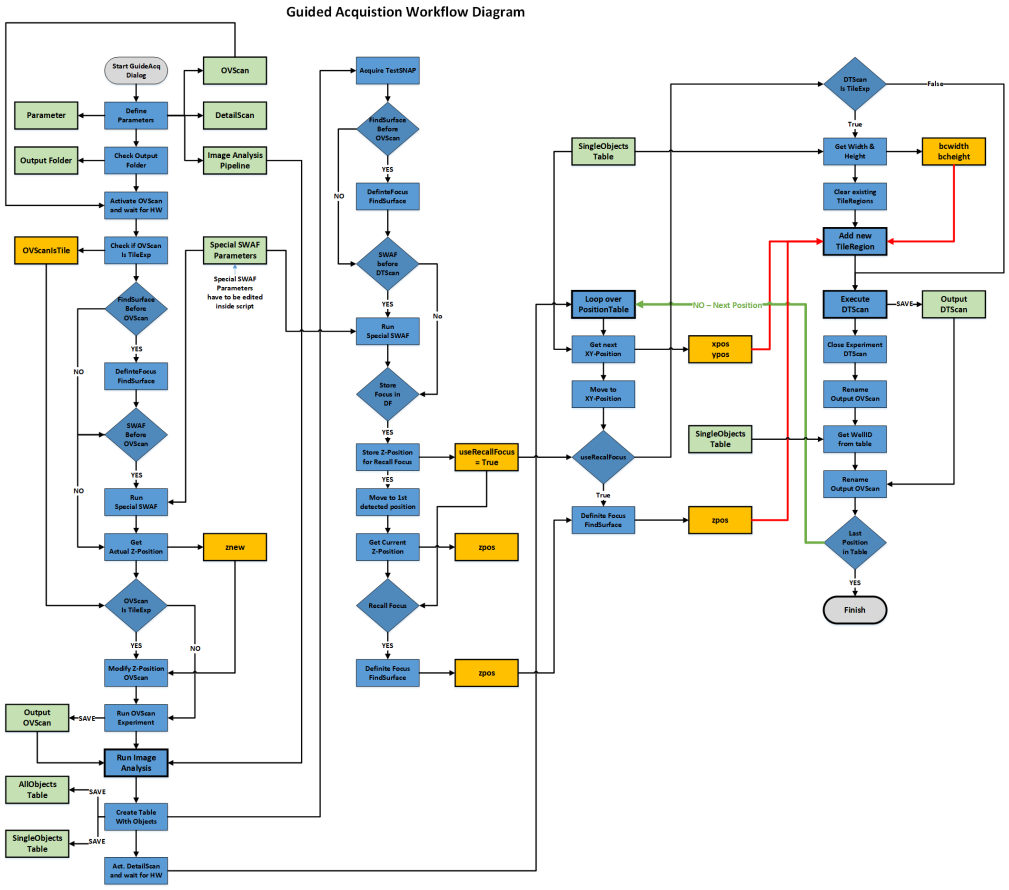

Figure 20: Completw workflow diagram for Guided Acquisition

7.2 Python Script: Guided_Acquistion_shortUI.py

This the the complete ZEN Blue python script used to realize the workflow describe above. In principle it can work on any motorized microscope stand running under ZEN blue (with some modifications), but it was tested and optimized mainly for the Celldiscoverer 7 and for the AxioObserver 7. Both of those stands have the Definite Focus 2 as an additional hardware option, which is strongly advised for such highly automated workflows, where fast and efficient focus options, such as Find Surface are really a big plus.

8 ToDo's and Limitations

The current version of this tool has still limitations and room for improvement.

- No yet built-in check to avoid double detailed scans for objects close to each other within one field of view.
- Currently only modification of rectangular tile regions are supported.
